First, it is good that you choosed a less known operating system.

To make it easier to the reader to understand your text, I think you should add som more details, and explain the solutions more in depth. For instance, you should not use the words «thing», «different kinds», etc. But rather give some concrete examples. Like wich kinds of roles can be assigned through the Trusted path-environment in Solaris? Which «things» can you perform in the Trusted path-environment?

You do mention the Trusted path - mechanism, but as far as I can see, you have not mentioned anything about how the user actually gets to the trusted path-environment. (Is there a set of key strokes? An icon to click on? Logon-session?).

-> I do not think this will be trivial to a reader who does not have Solaris background information.

You added an illustration to support your text, which is good. I think, however that you could describe the the main components in the Trusted path-environment more in depth.

In your references, you are refering to a book, which is a plus :) I recommend you to take a closer look at this, there are a lot of information, and could give you some of the deatails you need. I do also see you refer to Wikipedia, note that this is a secondary reference.

I can not give you a pass because, as far as I can see, you have not fully described the Trusted path mechanism in Solaris, and some will not be trivial to a reader whitout Solaris background information(see the above comments).

Mark: Fail.
